### **Executive Summary**

The objective of this study was to compare the construction processes of two homebuilding systems, structural insulated panels (SIPs) and conventional 2x4 stick-built. SIPs are made with insulative foam sandwiched between oriented strandboard (OSB). Energy studies have demonstrated that SIPs can produce more airtight and energy efficient homes. SIP suppliers also promise significant construction advantages, however, little scientific data is available to substantiate claims. The study focuses on the construction of two similar single-family homes, one SIP and one stick-built, built by Habitat for Humanity during Fall 1997. The study documents two key measures of construction performance, cycle time and labor man-hours. The study addresses only those activities on the construction site and focuses on the framing process (rather than finishing), since the primary impact of the building system occurs during framing.

The SIP home, built in Sedro-Woolley, Washington, was a 1,293 square-foot, four-bedroom home. The floor, walls and roof were constructed using SIPs. Panels were delivered to the construction site with many factory value-added features including pre-cut panels (length, width, gables, windows/doors openings), pre-framed window/door openings, and pre-installed splines in the wall panels. The 2x4 stick-built home, built outside Plains, Georgia, was a 1,064 square-foot, four-bedroom home. While the majority of the home was stick built on site, some sub-assemblies, including roof trusses and window frames, were completed in the Habitat "factory" in Americus. Floor framing was not required due to slab-on-grade construction.

After being normalized by the square footage in each home (to account for design differences), the data indicate that the SIP home saved 65% of the site labor when compared to the stick-built home. Cycle time savings are of similar magnitude. Volunteers were interviewed after framing the SIP house to gauge their perception of SIP construction. The results suggest that both construction professionals and other volunteers believed that SIPs reduced construction effort significantly, averaging about one-half the effort of conventional stick-built construction.

The conclusions that can be drawn from this study are limited due to sample size, different home designs, different volunteer crews, uniqueness of Habitat construction, and extensive factory value-added content for the SIPs. However, several factors discourage us from dismissing the results as a random: 1) similarity of the home designs, 2) expertise of the responsible contractors, and 3) magnitude of the observed savings. Therefore, we believe that the SIP building system can be highly efficient on the construction site, substantially reducing site framing labor and cycle time. However, attaining these benefits requires the following of the homebuilder: 1) use large panels (up to 24'x8'), 2) have panels delivered to the site ready to install (cut-to-size, framed window/door openings, installed splines) 3) use a construction crane, and 4) thoroughly plan both the home design and the construction process to capture the potential benefits. At the same time SIP manufacturers must support homebuilders by: 1) migrating construction tasks into the factory as premium, value-added product features, 2) strengthening the design-to-manufacturing link and upgrading quality systems to ensure that delivered panels meet homebuilder specifications and 3) controlling costs and prices to keep SIP homebuilding cost competitive at the systems level.

#### **Background, Objectives and Scope**

The objective of this report is to compare the construction processes of two homebuilding systems, structural insulated panels (SIPs) and conventional 2x4 stick-built. SIPs are made with insulative foam sandwiched between oriented strandboard (OSB). Energy studies have demonstrated that SIPs can produce more airtight and energy efficient homes. SIP suppliers also promise significant construction advantages, however, little scientific data is available to substantiate claims. This report summarizes findings from a study of the construction of two similar single-family homes, one SIP and one stick-built, built by Habitat for Humanity during Fall 1997. The study documents two key measures of construction performance, cycle time and labor man-hours. The study addresses only those activities on the construction site and focuses on the framing process (rather than finishing), since the primary impact of the building system occurs during framing.

#### The Two Homes

The SIP home was framed in Sedro-Woolley, Washington on August 15-16, 1997. The floorplan for the SIP home (Figure 1) featured 1,293 square-feet and four-bedrooms. SIPs were used to construct the floor, walls and roof. SIP plans are shown in Figures 2, 3 and 4. SIP floor panels were supported by a system of girders, creating a crawl space (Figure 2). Panels were delivered to the construction site with many factory value-added features including pre-cut panels (length, width, gables, windows/doors openings), pre-framed window/door openings, and pre-installed splines in the wall panels. Additional component and framing details are included in the construction process description in Appendix A. The 2x4 stick-built home was framed outside Plains, Georgia on October 16-18, 1997. The floorplan for the home (Figure 5) featured 1,064 square-feet and four-bedrooms. While the majority of the home was stick built on site, some sub-assemblies, including roof trusses and window frames, were completed in the Habitat "factory" in Americus. Floor framing was not required due to slab-on-grade construction. Additional component and framing details are included in the construction process description in Appendix B. Weather during the framing of both homes was excellent and did not affect framing activities.

### **Approach and Results**

Site construction processes were documented by direct observation and supplemented by video recording. Two engineers and two video cameras were active at all times. The study was limited to on-site, structural framing activities, concluding with panel erection for the SIP home and installation of exterior sheathing and insulation for the stick-built home. Interior walls for both homes were stick-built and are not included in the study. Some relevant framing activities were completed in the respective factories and were not included in the study. For the SIP home these included pre-cutting (length, width, gables, windows and doors), pre-framing for windows and doors, and pre-installation of splines in the wall panels. For the stick-built home these included sub-assembly of roof trusses and window frames.

The construction activities observed are described in Appendices A and B. Start and completion times were recorded for all activities as well as the number of personnel involved. When personnel changed during the course of an activity, the change and time of change were noted. From these data, precise estimates of activity duration (minutes) and labor (man-minutes) were developed for each activity. When more than two activities were simultaneously underway, engineers cycled frequently between activities. Detailed data are shown in Appendices C and D.

Before summarizing and discussing these results, it is important to emphasize the unique nature of Habitat construction. Volunteers build each home under the guidance of an experienced homebuilder. Construction of the SIP home was guided by a nationally recognized contractor credited with building over 600 SIP homes. An experienced Habitat builder directed construction of the stick-built home. Over 50 volunteers participated in the construction of each home, serving as workers, greeters and construction coordinators. Volunteers arrived and departed continuously throughout the process. Volunteer profiles are shown in Figures 6 and 7. Data were obtained by interviewing volunteers after framing was completed. The data indicate that both jobs had volunteers with a wide range of construction experience, from novices to highly experienced professionals. The data also suggest that the construction experience of volunteers was reasonably comparable for both jobs. An important factor not evident in the data is that the volunteers for the SIP home had no prior SIP construction experience.

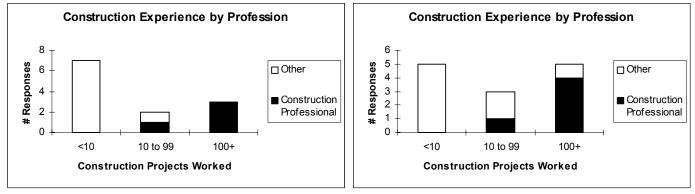

Figure 6. Construction experience of volunteers for stick-built home

The unique nature of the Habitat workforce often resulted in less than ideal efficiency on the construction site. More than 10 volunteers routinely moved and positioned large SIPs, when significantly fewer could have moved the panels safely and efficiently. Construction activities were routinely accomplished in series (one-at-a-time), rather than in parallel, so that the expert could ensure both safety and quality. In several cases the expert asked volunteers to rework unacceptable product. To maximize safety (and possibly because of the abundance of labor), Habitat has a policy of limiting the use of nailguns. The only exception to this policy was a .22 caliber nailgun used to attach wall bottom plates to a concrete slab in the stick-built home.

Results for the SIP home are summarized in Table 1. The activities required a cycle time of 1,053 minutes (18 hours) and labor of 7,194 man-minutes (120 man-hours). The floor required the most effort (39%), followed by the roof (27%). Framing the support structure for the floor and roof panels accounted for over 60% of this effort.

	Fram	ning	Panel	izing	То	tal	
Activity	Cycle Time	Labor	Cycle Time	Labor	Cycle Time	Labor	
	(Minutes)	(Man-Min)	(Minutes)	(Man-Min)	(Minutes)	(Man-Min)	
Unload	0	0	205	820	205	820	11%
Floor	265	1,750	148	1,032	423	2,782	39%
Walls	0	0	279	1,678	279	1,678	23%
Roof	367	1,137	208	777	596	1,914	27%
Total	NA	2,887	NA	4,307	1,053	7,194	100%

Table 1. Summary results for SIP home

Results for the stick-built home are summarized in Table 2. The activities required a cycle time of 2,016 minutes (34 hours) and labor of 8,421 man-minutes (140 man-hours). The roof required 62% of the effort.

Activity	Cycle Time	Labo	or			
	(Minutes)	(Man-Minutes				
Wall	1202	3219	38%			
Roof	1026	5202	62%			
Total	2016	8421	100%			

Table 2. Summary results for stick-built home

Several factors must be considered when comparing the two sets of construction results. First, unloading of materials was not observed for the stick-built home. Second, the design of the homes, though similar, were different:

- The SIP home was over 20% larger than the stick-built home.
- The SIP home had a crawl space, requiring a framed floor. The stick-built home utilized slab-on-grade construction, which did not require a framed floor.

Since the SIP home could have used the same design specifications as the stick-built home, reducing cycle time and labor requirements, it is important to normalize results. Table 3 summarizes results for comparable activities and Table 4 shows normalized results based on square footage.

		SIP		Stick-Built				
Activity	Cycle Time	Labor		Cycle Time	Labor			
	(Minutes)	(Man-Minutes)		(Minutes)	(Man-Minutes)			
Wall	279	1678	47%	1202	3219	38%		
Roof	596	1914	53%	1026	5202	62%		
Total	774	3592	100%	2016	8421	100%		

Table 3. Summary results for comparable activities

	:	SIP	Stic	k-Built	SIP Savings		
Activity	Cycle Time	Labor	Labor Cycle Time Labor		Cycle Time	Labor	
	(Min./sqft)	(Man-Min./sqft)	(Min./sqft)	(Man-Min./sqft)	(Min./sqft)	(Man-Min./sqft)	
Wall	0.22	1.30	1.13	3.03	.91	1.73 (57%)	
Roof	0.46	1.48	0.96	4.89	.50	3.41 (70%)	
Total	0.60	2.78	1.89	7.92	1.29	5.14 (65%)	

Table 4. Normalized summary results for comparable activities

The normalized data indicate that the SIP home saved 65% of the site labor when compared to the stick-built home. Cycle time savings are of similar magnitude. Savings in roof construction was 70%, while wall savings totaled 57%.

Table 5 provides additional detail about panel-related construction activities for the SIP home. In addition to the effort required to frame the panel support structure for the floor and roof (described earlier in Table 1), modifying, positioning and fastening panels also required considerable effort. Modification was required on several wall panels due to a miscommunication between design and manufacturing at the manufacturing plant. Panels were fastened using splines, requiring construction adhesive and nails. Adhesive was applied using a caulking gun and nails were driven by hammer. Table 5 also provides per panel averages for all panel-related activities.

Table 6 provides additional detail about construction activities for the stick-built home. Note that sheathing accounts for 38% of all effort, primarily due to manual handling and nailing (no nailguns). Framing accounts for another 18% the effort.

	Floor				Walls	Ro			Roof		Total

Table 6. Detailed summary of construction activities for stick-built home

Volunteers were interviewed after framing the SIP house to gauge their perception of SIP construction. The results (Figure 8) suggest that both construction professionals and other volunteers believed that SIPs reduced construction effort significantly, averaging about one-half the effort of conventional stick-built construction. Additional comments from the volunteer interviews are provided in Table 7. It should be noted that many volunteers had significant construction experience, including experience as professionals, but no volunteers had previous experience with SIPs.

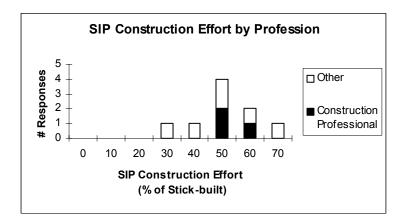

Figure 8. Volunteer perception of SIP construction effort compared to stick-built

Construction Professionals	Non-Construction Professionals
Environmentally sound; dimensional lumber more	Solid bottom is plus; insulation doesn=t sag
valuable for other things	and no animal infiltration
Impressive	Less squaring and nailing
Durability, especially with temperature change?	Less labor; simple to build
Remodeling?	Foam recyclable?
Quick framing; no need for additional insulation	Effect on ecology?
Strength without studs, especially with tile roof?	Easy from organizational standpoint
Good idea	Not much learning required
Needs airflow?	Airtight
Unlimited design	More efficient, but probably more expensive
Serious contender	Wonderful construction technique
Cost-benefit analysis needed?	Water damage?
Problems with subs?	Environmental issues? Recyclable?
	Well-insulated floor
	Electrical wiring?
	Faster; maybe better
	Fewer places to adjust
	Fewer joints

Table 7. Volunteer comments and perceptions about SIP construction

### **Other Construction Measures**

Several additional types of construction data were collected during the construction of the two homes. The first was the heavy equipment used. SIP construction required the use of a crane and a forklift was also used. The stick-built home required no heavy equipment. Heavy equipment information for the SIP construction process is shown in Table 8.

			Elapsed Time	Start of Use	End of Use	Duration of Use
Item	Arrive on Site	Depart Site	on Site (min.)			(min.)
Forklift	Day 1, 8:00am	Day 2, 7:00pm	1027	Day 1, 9:00am	Day 2, 7:00pm	967
Crane	Day 2, 10:00am	Day 2, 7:00pm	480	Day 2, 1:46pm	Day 2, 7:00pm	314

Table 8. Heavy equipment usage during construction of the SIP home

Material usage and waste was collected during construction of the SIP home (Table 9). Material, including waste, was counted before starting and after completing framing. Waste was termed 'potential' since Habitat attempts to re-use all excess materials. Potential waste was separated into two categories: less than and greater than two feet in length. The rationale is that the longer scrap is more likely to find a use on the current or a future construction site. Since all SIP fabrication occurred in the factory, a theoretical calculation of factory trim waste is included. Material usage was less controlled on the stick-built site. Three homes were being built simultaneously and it was impossible to accurately monitor overall usage and waste. Very little waste was observed during construction of the stick-built home.

	Potential Waste											
ltem	Usage	Length < 2'	% of Use	Length > 2'	% of Use	Total	% of Use

Table 9. Material usage and potential waste for the SIP home

### Conclusions

The conclusions which can be drawn from this study are limited by many factors:

- Sample size one home for each building system
- Non-identical home designs
- Different volunteer crews
- Uniqueness of Habitat construction
  - Volunteers of various skill levels
  - Overabundance of labor
  - Limited nailgun usage
- Heavy factory value-added content for the SIPs

However, several factors discourage us from dismissing the results as a random data point.

- The similarity of the designs
- The expertise of the responsible contractors
- The magnitude of the observed savings

The SIP building system can be highly efficient on the construction site, substantially reducing site framing labor and cycle time. However, attaining these benefits requires the following of the homebuilder:

- 1. Use large panels of up to 24'x8'.
- 2. Have panels delivered to the site ready to install: cut-to-size, framed window/door openings, and installed splines.
- 3. Use a construction crane to install panels.
- 4. Thoroughly plan both the home design and the construction process to capture the potential benefits.

At the same time, SIP manufacturers must support homebuilders by:

- 1. Migrating construction tasks into the factory as premium, value-added product features.
- 2. Strengthening the design-to-manufacturing link and upgrading quality systems to ensure that delivered panels meet homebuilder specifications.
- 3. Controlling costs and prices to keep SIP homebuilding cost competitive at the systems level.

## Appendix A Construction Process Description for SIP Home

#### Unload

**1. Unload 2x6 lumber:** 2x6 lumber was delivered to the site on the same load as the SIPs. Lumber was unloaded using a large forklift. Four people were involved in the process. Two climbed onto the load, one supported the operation from a ladder, and one person operated the forklift. The person who was on the ladder also helped in transporting and setting down the load.

**2. Unload SIPs:** The structural insulated panels (SIPs) were unloaded from the delivery truck in much the same way as lumber. This operation was one of the more hazardous operations due to the size of the panels and the height and precariousness of the people on the truck. SIPs were placed in an open field on the right side of the house.

#### Floor

**1. Lay plastic ground cover:** Black polyethylene plastic was spread over the ground as a moisture barrier. The process was interrupted by a break for prayer and introductions.

**2. Level:** Planning involved checking the height of the nine steel Simpson post bases which were permanently mounted in the poured concrete piers. Two persons did this, one operating a theodolite and the other holding a measuring tape at the pier.

**3. Prepare post for master bedroom:** The post supporting the girders for the master bedroom were made by joining two 2x4s (using nails and glue). Two additional 2x4s were nailed on the sides at the top of the post to form a cavity for the girders. The post was placed on the Simpson Strong Tie post (NER393). OSB was used as shims to adjust for height.

4. Prepare remaining posts: The remaining posts were made following the same procedure.

**5.** Cut 2x10 laminated veneer lumber (LVLs) for girders: LVLs were cut-to-size by 2-3 persons using sawhorses and a circular saw.

**6.** Make girders by joining 2x10s: Girders were made by nailing and gluing two 2x10 LVLs. This operation was performed by 2-6 people. The process was lengthy because of hand nailing.

**7. Transport and position girders for master bedroom** : Girders were transported and positioned by hand, supported by the post and the concrete wall.

**8. Modify girder 2M for master bedroom:** One girder for the master bedroom was too long and had to be re-cut using a circular saw.

**9. Transport and position remaining girders:** Girders were transported and positioned as described previously.

**10. Modify remaining girders:** Some girders were too long and were trimmed using a circular saw.

11. Nail girders together: Abutting girders on a post were joined with a strap and nails.

**12. Gusset girders for the master bedroom:** Girders were gusseted using an OSB gusset plate placed at the T-joint formed by the girders and the post.

**13. Modify sill plates:** To provide a more continuous support for the floor panels, 2x4s were placed on top of sill plates and girders. To accomplish this, the sill bolts were recessed by creating a cavity in the sill plates and re-tightening the bolts. This was done by 2-3 persons using hand tools.

**14.** Attach 2x4s on top of girders and sill plate: 2x4s were positioned and nailed to the top of girders and sill plates to provide more continuous support for panels.

**15. Transport floor panels:** Floor panels were transported manually to the perimeter of the house.

**16. Apply adhesive to spline:** Note that the 2x6 splines were pre-assembled in the floor panels. Adhesive was applied only to the top-side of the spline.

**17. Position panels:** Panels were positioned and snugged using a come-along and sledge hammer.

**18. Fasten panels:** Ten inch screws were used to fasten panels to sill plates and nails were used for fastening panels along the splines. Note that the 2x6 splines were pre-assembled in the floor panels so that only one seam of nails was used on the top-side of the joint.

**19. Tighten panel screws:** Long screws were tightened to prevent interference with bottom plates.

#### **Exterior Walls**

**1. Snap lines for exterior walls:** Lines were snapped to position bottom plates for exterior walls. Two persons used the chalk string.

**2.** Attach bottom plates for exterior walls: 2x6 bottom plates were transported, measured, cut-to-size, positioned and glued/nailed to the floor panels.

3. Apply adhesive to the bottom plate and spline: Adhesive was applied to the outside side of

the bottom plate and spline using a caulking gun in preparation for setting the wall panel.

**4. Transport wall panel:** Each wall panel was manually carried to the point of use. This operation involved 10 or more people.

**5.** Set the wall panel on the bottom plate: Each wall panel was placed on top of the bottom plate after adhesive was applied. This process involved 10 or more people.

**6. Snug the panel:** Each wall panel was snugged to the adjacent panel using a come-along and a sledge hammer.

**7. Fasten panel to bottom plate and spline:** Each wall panel was attached to the bottom plate and the spline of the adjacent panel using nails and a hammer. Note that 2x6 splines were pre-assembled in the wall panels so that only one seam was nailed per joint (both inside and outside). Also note that openings for windows and doors were pre-cut and framed in the factory using 2x6s.

8. Insert corner post: One corner post was added to WD1.

**9. Modify panel:** Panels forming the front and rear walls of the house required modification. The ends of the panels were cut using a circular saw and foam was stripped using a hot melt tool to form a spline channel. The reason for the modifications was a last minute change in foam supplier, which led to a change in wall depth. The change was not compensated for in the manufacturing plans.

## Roof

**1. Snap lines for interior walls:** Lines were snapped to position interior walls and holes for posts that are embedded in the walls. Two persons used the chalk string.

**2.** Cut holes for posts: Holes were cut in the floor panels. Cuts were made through the top OSB skin and the foam. This operation was performed using a power saw.

**3. Erect posts to support ridge beams:** Posts used to support the ridge beams were assembled using two 2x6s sandwiching an OSB strip. Components were moved to the point-of-use, measured, cut-to-size, and assembled using nails. Posts were then erected, leveled, and braced using temporary supports. This operation involved 5 people.

**4. Place ridge beams and re-square posts:** Each ridge beam was lifted from outside the house using a crane and placed between the ridge beam and the wall. A cavity for the ridge beam was pre-cut in the wall. The post was then re-leveled. The middle beam rested on two posts and was placed after the supporting posts were properly aligned.

**5. Final check and adjustment of the beam:** After the two beams were placed in the post, the post was again leveled and nailed using a metal strap.

**6.** Apply adhesive to top of wall panel: Before the roof panel was placed, adhesive was applied to the top of the wall panels. This was done by 1-2 people using a caulking gun.

**7. Prepare roof panel:** Before lifting, each roof panel was prepared at ground level. Preparation involved snapping lines (to facilitate final positioning), starting 10@ screws along this line, and attaching 2x4s. 2x4s were used to attach the lifting hook and to serve as a safety stop for roof workers.

**8. Lift roof panel:** Each panel was lifted and positioned by crane. The process required 4 people, one crane operator and three guiding and adjusting before fastening the screws. On occasion one person had to stand on a ladder from the outside and give support for fine adjustments.

**9. Fasten the roof panel:** The roof panel was fastened by driving the pre-started 10" screws into the wall panel and the ridge beam. The two OSB splines (per joint) were then inserted from the end into the factory-made spline channels. On several panels, splines were placed on the installed panel before the next panel was lifted. The former procedure proved to be more effective and it was adopted for the remaining panels. Some splines were inserted with adhesive applied; however, it required considerable effort to overcome the friction and the practice was discontinued on later panels. Note that no glue was used on splines for these panels. After inserting the splines, the joint was fastened using nails from the top side (2 rows of nails, one row on each panel). Note that the bottom spline was not fastened.

**10. Prepare splines:** Spline preparation involved the application of the glue on the spline before inserting it in the spline channel. This was not done for all splines and required one person.

**11. Modifying the panel:** Several panels had to be re-cut to accommodate the porch which was not in the original plan. This was done using a circular saw and a hot-melt foam cutter.

## Appendix B Construction Process Description for Stick-built Home

#### Walls

**1. Snap lines**: The location for each wall was determined using a tape measure. A chalk line was snapped on the concrete slab to mark the precise location. (2 persons)

**2. Transport 2x4s**: 2X4s used to frame each wall were manually carried from a lumber staging area to the wall location on the slab.

3. Frame: Each wall was framed horizontally on the slab.

4. Sweep slab: The slab where each wall was to be erected was swept using a broom. (1 person)

**5.** Apply sealant: After the slab was swept, silicone rubber sealant was applied to the slab using a caulking gun. (1-2 persons)

**6. Erect wall frame**: Each wall frame was erected manually on the slab on top of the sealant. The wall was manually held in position until 3-4 nails were fired into the slab using a .22 caliber nail gun.

**7. Tie wall to the ground**: After each wall was erected, it was tied to the ground using a 2x4 that was nailed to another 2x4 hammered into the ground.

8. Nail frame to slab: When the wall was secure, the nail gun was used to add nails.

**9.** Cut OSB for wall corners: OSB was used at wall corners for racking strength. 3/8" OSB was cut to the required dimensions using a table saw.

**10. Nail OSB to the frame**: Cut OSB was nailed to the corners of the wall frame using a hammer.

**11. Nail anchors to the frame**: Anchors (Mud Sill Anchor, No FA3) which were already attached to the slab were nailed to the wall frame using a hammer.

**12.** Nail horizontal 2x4s: Wall frames were connected with horizontal 2x4s to serve as a backing for the interior walls. Hammers were used.

**13.** Nail top plate: 2x4 top plates were used to tie wall frames. Plates were nailed by persons working on ladders using hammers. (1-2 persons)

**14. Nail R3 Styrofoam as outer wall sheathing**: R3 Styrofoam was nailed to the wall frame using a hammer.

**15. Install batt insulation**: Process not observed. Estimates obtained from local contractor.

#### Roof

**1. Prepare beams for porch**: The porch beams were prepared by nailing two 2x8s sandwiching 3/8" OSB. The 2x8s were first cut to the required size by the table saw and then they were nailed together.

**2. Erect and square beams**: The porch beams were manually lifted, positioned at the proper location, squared using a level, and nailed.

**3.** Add face plate to gable ends: The gable ends were nailed with a 2x4 face plate on top of the top plate (2" offset to the exterior edge).

**4. Nail Styrofoam on the gable trusses**: The gable trusses were nailed with R3 Styrofoam. The Styrofoam was nailed and then cut to match the outer truss profile using the cutter.

**5. Remove gusset plates from second truss**: The second gable truss had gusset plates on both sides. Gusset plates were removed from one side using a chisel and a hammer.

**6.** Square walls: Before installing trusses, the walls were squared using a level. When squared, the frame was nailed to the slab using an inclined 2x4 extending from the top of the wall to the slab on the inside of the frame.

**7.** Lift trusses: Each truss was lifted manually by 6-8 persons. It was then supported by a 2x4 until 3 topside persons could place it horizontally, resting on the walls.

**8. Erect trusses**: The trusses were erected manually, squared and nailed to the walls on 24" centers. A 1x4 running on top of the trusses was used for support.

**9. Nail truss hangers (E.F.1, HC-1, NER-408)**: Once trusses were set, the trusses were joined to the walls using truss hangers.

10. Nail catwalk: 2X4s were nailed between two adjacent trusses for a catwalk.

11. Cut 2x4 for lookouts: 2x4s used to form lookouts were cut using a table saw.

**12. Hang lookouts:** The cut 2x4s were nailed to the gable end trusses using a hammer.

**13.** Cut Styrofoam for doors and windows: The Styrofoam on the exterior walls covering doors and windows was cut using a cutter.

**14. Lift 2x6s and nail to the lookouts**: 2x6s were attached at the outer end of the lookouts. They were lifted manually by three people and nailed using a hammer.

15. Place and nail roof sheathing: The roof sheathing, 1/2" OSB, was transported to the roof and

nailed. Sheathing was added in rows beginning on the outer edges. Enough OSB for one row was lifted and nailed to the trusses.  $\frac{1}{2}$  " roofing clips were placed between adjacent rows of OSB, 2' on center. (6 persons)

16. Install batt insulation: Process not observed. Estimates obtained from local contractor.

- 2. Duration (cycle time) is defined as clock time (min.) between the start of an activity and its end. The activity may not be continuous over the duration. Formal breaks (including overnight) are subtracted from duration.
- 3. A small number of activities were not observed. Estimates for these activities were made from similar activities.

## Acknowledgement

This research was sponsored by the U.S. Department of Energy, Office of Building Technology, State and Community Programs - - Energy Efficient Industrialized Housing Program. We appreciate the encouragement and support of our program manager, Mr. George James.

We also appreciate the cooperation and efforts of Ms. Cynthia Gardstein, Executive Director of the Structural Insulated Panel Association (SIPA), Mr. Bill Garner, Executive Director of the Skagit Habitat for Humanity, and the many volunteers who participated in the construction.
